Abstract

The Northern Mediterranean region includes a wide range of climatic variability, and a spectrum of economies that have entered the EU at different times. This study attempts to increase understanding and predictability of both the Mediterranean climate and the potential for climate derived socio-economic impacts a selection of these economies may face. A methodology is detailed whereby the target region is assessed for the patterns and causes behind extreme climatic events (that may challenge current adaptation strategies), and the kinds of socio-economic outcomes that they may produce.

In order to explore the behaviour of floods, droughts, heatwaves, and cold snaps, across the Northern Mediterranean region (35°-45°N, -10°-30°E) with a selection of hemispheric circulation predictors (drawn from the NCEP/NCAR reanalyses), two differing models have been used. Orthogonal Spatial Regression (OSR) is an inversion of a dendroclimatology technique that relies on spatial variability, with Principal Components Analysis (PCA) at its core. Radial Basis Function Artificial Neural Networking (RBF ANN) is a machine-learning pattern matching approach, capable of non-linearity. The two have been applied as direct downscaling methods to the STARDEX (STAtistical and Regional dynamical Downscaling of EXtremes for European regions) indices of extremes, across the target area. Analysis suggests that there may be significant departures between regional and seasonal contrasts in extreme behaviour, and those evident for mean climate. In addition, where warming occurs, extreme high temperatures generally show a trend of greater magnitude than the mean. Modelled links between circulation predictors and extreme climate are consistent with these results, statistically significant, largely linear, and are (in many cases) stronger for extremes than the mean. Distinct circulation regimes have been identified, as described by groups of predictors (representative of Atlantic influence, for instance), each with effects that are relevant to a particular region, season, and type of Mediterranean extreme climate.

This thesis also explores direct relationships between extreme events (quantified by the indices of extremes) and socio-economic indicators (i.e., agricultural yield, energy consumption, and excess mortality). OSR and ANN are applied again, as econometric upscaling models, between climate indices and socio-economic indicators, to provide the final link in a chain of potential predictability. Long-term (i.e., decadal) trends in the socio-economic indicators considered are consistent with non-climatic influences. However, regional variations in sensitivity to extreme climate have been identified (on a seasonal basis) that demonstrate both the advantages of using upscaling technique, and the use of station-scale predictors over spatially aggregated data. The model functions (e.g. linear, gaussian, or quadratic) most useful for modeling relationships are seen to vary between regions and seasons. Furthermore, regions that display strong trends in extreme behaviour and significant links to sensitive sectors of activity have been highlighted. This study suggests that Mediterranean climate extremes are changing over time, and that policy concerning the socio-economic impacts of those changes must be specified with regional concerns in mind.

Acknowledgements

I would like to thank my supervisors, Dr. Clare Goodess, and Prof. R. Kerry Turner for their diligence, rigour, and support. I would also like to thank Prof. Phil Jones for providing many insightful comments on the climate side of this thesis.

Various members of the Climatic Research Unit have provided invaluable advice and aid during my time here, in particular Jean Palutikof, Mike Salmon, Ian Harris, and my office mates - David Foxall, Carol McSweeney, Ali-Reza Massah, Amanda Townsend, and Kate Willet.

The data used for this thesis have been acquired from several sources. Daily climate data were compiled from sets provided by members of the STARDEX project, FIC, KNMI, the U.K. Met Office, and the Bosnian and Slovenian Meteorological Offices. Both NCEP/NCAR reanalysis data (Ian Harris), and the NAO index time series (Phil Jones) were provided by CRU. Fotis Panagiotopoulos supplied the Siberian High index data. Data regarding extreme climate events were acquired from Munich Re, and OFDA/CRED (the Em-dat database). The databases of Eurostat, the World Bank, the WHO, and the FAO were used to develop the socio-economic indicators in Chapter 6.

Phil Jones and Keith Briffa wrote the original Orthogonal Spatial Regression Fortran program developed here, Colin Harpham wrote the Radial Basis Function Artificial Neural Network C++ program, and Malcolm Haylock wrote the Indices of Extremes program (for the STARDEX project), used to calculate climate indices in Chapter 3.

In addition to the above I would also like to thank my kind and patient friends in both Norwich and parts distant, particularly for much needed opportunities to let off steam. Final mention goes to my family, who have provided essential assistance in times of trouble, endless encouragement, and most importantly, inspiration.

List of Acronyms

AIR	All India Averaged Rainfall	EU-ETS	EU Emission Trading
ANN	Artificial Neural Networks	EAO	Scheme
AYA	Agricultural Yield per hectare Anomaly	FAO	Food and Agricultural
BLUE	Best Linear Unbiased	FIC	Organization Fundación para la
DLUE	Parameters	TIC	Investigación del Clima
BOSR	Basin OSR	GBF	Gaussian Basis Function
CAP	Common Agricultural Policy	GCM	General Circulation Model
CCA	Canonical Correlation	GDP	Gross Domestic Product
	Analysis	GNP	Gross National Product
CDD	Cooling Degree Days	HadCM	Hadley Centre Coupled
CLR	Classical Least-squares		Model
	Regression	HadRM3	Hadley Centre Regional
CO_2	Carbon Dioxide		Model 3
CRU	Climatic Research Unit	HDD	Heating Degree Days
DEFRA	Department for	hPa	hectoPascals
	Environment, Food, and	HGT	Geopotential HeiGhT
	Rural Affairs	IPCC	Intergovernmental Panel on
	Diurnal Temperature Range		Climate Change
DTR	East-Atlantic West-Russia	ITCZ	Inter-Tropical Convergence
E A WD	pattern	TT A	Zone
EAWR	European Climate	JJA	June, July, August
ECA	Assesment	KNMI	Koninklijk Nederlands
ECA	ECA and Dataset	LBF	Meteorologisch Instituut Linear Basis Function
ECA&D	Commerical Electricity Consumption	MAM	March, April, May
ECC	European Centre for	mb	millibars
LCC	Medium-range Weather	MEI	Multivariate Enso Index
ECMWF	Forecasting	MICE	Modelling the Impact of
ECIVI VVI	European Coal and Steel	WHCL	Climate Extremes
	Community	MLP	Multi-Layer Perceptron
ECSC	European Economic	MO	Mediterranean Oscillation
	Community	MO(AC)	MO for Algiers and Cairo
EEC	Emergency Disasters Data	MO(GI)	MO for Gibraltar and Israel
	Base	MPI	Mediterranean Pressure
EM-DAT	Excess Mortality Index		Index
	El Niño-Southern	MSLP	Mean Sea Level Pressure
EMI	Oscillation	NADW	North Atlantic Deep Water
ENSO	Empirical Orthogonal	NAO	North Atlantic Oscillation
	Function	NCAR	National Center for
EOF	ECMWF ReAnalysis		Atmospheric Research
ED A	Residential Electricity	NCDC	National Climatic Data
ERA	Consumption	MOED	Center
ERC	European Union	NCEP	National Centers for
EII		NIO A A	Environmental Prediction
EU		NOAA	National Oceanic and
			Atmospheric Administration
